Dysfunctional Patterns & Trauma

- **Dysfunction**: settings where individuals engage in behavior that is inconsistent or unpredictable, creating chaotic environments; includes: domestic violence, physical abuse, sexual abuse, or verbal abuse, displays of power, and spreading of misinformation / myths.

- **Trauma**: condition resulting from any experience of violence, which constitutes an assault against one’s physical body, self-concept, identity, cognitions, affects, and consciousness.
The “Three-Factors”

- In examining the impact of trauma on mental health:
  - 34 - 53% of SMI people report a history of trauma
  - Among those with co-morbid AOD: 43% of women, 12% of men with trauma history
  - CSAT estimates that 2/3 of women and men in treatment have a history of childhood neglect
  - One study reported 20% of women entering MH or AOD treatment had the “triple diagnosis;” of those, 70-85% had a history of MH or AOD treatment in the past 5 years.
Intersecting Factors

- Greater likelihood of physical & sexual trauma among those with mental disorders – especially women
  - Up to 7 times more likely to experience a sexually abusive incident
  - 80% of assaults are committed by an acquaintance

- Women are also more likely to report a physically abusive incident – 3:1 over men
  - 22% of women
  - 7% of men

At least 60% of women in substance abuse treatment report having been abused (physically or sexually) at least once (50% - 92%).

A significant number of women in AOD treatment report having experienced multiple incidents of abuse.
Child Sexual Abuse

- Exploitation/victimization of child under 18 years of age by an adult, adolescent, or older child
  - Determined to be abuse based on difference in
    - Age
    - Sexual knowledge, ability to consent

- Incest involves sexual contact between family members

- Prevalence
  - 1 in 3 girls
  - 1 in 6 boys are sexually abused by age 18

Differences in Rates of Mental Health Diagnoses

- **Women (examples)**
  - Depression (3x)
  - Trauma-related PTSD
  - Borderline Personality Disorder
  - Eating Disorders
  - Phobias
  - Anxiety-Disorders (2x)

- **Men (examples)**
  - Schizophrenia
  - Anti-social Personality disorder
  - War/combat-related PTSD

Mental Health & Substance Use

- Nearly twice rate of general population (14% vs. 28%)
  - Can vary by DSM-IV diagnosis, patterns of “drugs of choice”

- “Self-medication” of untreated/undiagnosed mental disorders
  - Minimize symptoms: depression, anxiety
  - Similar chemical action in brain with neurotransmitters
  - Help to forget about abuse, reduce flashbacks, etc.
Chemical Factors Related to Mental Illnesses, AOD Use

- Physiological Aspects: characterize both men & women
  - Chemical differences in the brain related to neurotransmitters:
    - Dopamine
    - GABA
    - serotonin, norepinephrine, & acetylcholine
- Same chemicals in the brain have been empirically linked to presentation of schizophrenia, depression, bipolar disorder, and other mental health problems.

Most Common Emotional Impact of Abuse

- **Post Traumatic Stress Disorder (PTSD)**
  - Reactions can occur months or years after an incident

- Also higher rates of depression, dissociative disorders, anxiety disorders, self-mutilation, attempted suicide, and low-self-esteem than general population studies

Substance Abuse & PTSD

- One study of women in SA treatment showed that women who also had PTSD had more severe clinical profile (multiple issues)
  - Worse life conditions (as child and adult)
  - Greater criminal behavior
  - Higher number of lifetime suicide attempts
  - Sibling with substance abuse problem

Assessing Trauma

- Individual has active symptoms of PTSD, begin to address them immediately
- During initial 30 days in treatment, client becoming engaged in treatment
  - Assess for ongoing DV
  - Not optimal for dealing with trauma, unless client unable to maintain abstinence
- 2nd stage of recovery, 30 days to 2 years
  - Client engaged in treatment
  - Some support systems in place

Trauma assessment

- Client’s may not reveal trauma histories
  - Shame
  - Suppressed memories
  - Minimize experiences
  - Concerns about confidentiality
  - Trust
  - Triggers

“It is fearful to disclose abuse. Your risk being judged, being penalized, being discredited, invalidated, and having your feelings minimized.”

Trauma Assessment

- Must re-assess as treatment progresses
- Prepare clients that talking about such issues may be uncomfortable
For Disclosure:

- Have appropriate support available in case crisis occurs during disclosure
  - Accessibility of mental health practitioner

- Assess how client is feeling about disclosure
  - distraught?
    - Assess for suicidal ideation

- Assess sources of emotional and social support available to clients. Provide referrals for appropriate support services

After Disclosure:

- Client’s may be hypersensitive after disclosure, may need reassurance that counselor does not hold them responsible for abuse or think of client differently.
- Client’s who suffered severe or recent abuse may need reassurance that they are safe.
- Some clients may require inpatient or intensive outpatient programs initially to deal with overwhelming feelings of rage, anxiety, depression, shame, or suicidality.

Triggers – often catalyze use

- Discuss coping strategies
  - Deep breathing, relaxation, physical exercise, talking about feelings, grounding exercise
  - Help them plan ahead for situations that may trigger a trauma related reaction
  - See what strategies are more effective for client

- Help identify ways to promote feelings of control in trigger situations

Components of Comprehensive Drug Abuse Treatment

The best treatment programs provide a combination of therapies and other services to meet the needs of the individual patient.
